

Interface

- An Interface is defined using the `interface` keyword
- Interfaces are used only during compilation time to check types
- By convention, interface definitions start with an `I`, e.g. : `IPoint`
- Interfaces are used in classical object oriented programming as a design tool
- Interfaces don't contain implementations
- They provide definitions only
- When an object implements an interface, it must adhere to the contract defined by the interface
- An interface defines what properties and methods an object must implement
- If an object implements an interface, it must adhere to the contract. If it doesn't the compiler will let us know.
- Interfaces also define custom types

Basic Interface

Below is an example of an Interface that defines two properties and three methods that implementers should provide implementations for:

```
1 interface IMyInterface {  
2     // some properties  
3     id: number;  
4     name: string;  
5  
6     // some methods  
7     method(): void;  
8     methodWithReturnVal(): number;  
9     sum(nums: number[]): number;  
10 }
```

Using the interface above we can create an object that adheres to the interface:

```

1 let myObj: IMyInterface = {
2   id: 2,
3   name: 'some name',
4
5   method() { console.log('hello'); },
6   methodWithReturnVal () { return 2; },
7   sum(numbers) {
8     return numbers.reduce( (a,b) => { return a + b } );
9   }
10 };

```

Notice that we had to provide values to **all** the properties defined by the Interface, and the implementations for **all** the methods defined by the Interface.

And then of course you can use your object methods to perform operations:

```

1 let sum = myObj.sum([1,2,3,4,5]); // -> 15

```

Classes as Interfaces

Because classes define types as well, they can also be used as interfaces. If you have an interface you can extend it with a class for example:

```

1 class Point {
2   x: number;
3   y: number;
4 }
5 interface Point3d extends Point {
6   z: number;
7 }
8 const point3d: Point3d = {x: 1, y: 2, z: 3};
9 console.log(point3d.x); // -> 1

```

First we are defining a class called `Point` that defines two fields. Then we define an interface called `Point3d` that extends the `Point` by adding a third field. An then we create a point of type `point3d` and assign a value to it. We read the value and it outputs `1`.
