Data Modeling and State

- Angular is flexible and doesn't prescribe a recipe for managing data in your apps
- Since observables are integrated into Angular, you can take advantage of observables to manage data and state
- You ca use services to manage streams that emit models
- Components can subscribe to the streams maintained by services and render accordingly.
 - For example, you can have a service for a Todo app that contains a stream of todos and a ListComponent can listen for todos and render when a new task is added.
 - You may have another component that listens for the user that has been assigned to a task provided by a service.
- The steps for creating different parts of an app can be summarized in three steps:
 - Defining a Model using a class
 - o Defining the service
 - Defining the component

Observables

- Angular embraces observables using the RxJS library.
- Observables emit events and observers observe observables.
- An observer subscribes to events emitted from an observable.
- RxJS has an object called *subject* that can be used both as an observer or an observable. Subject can be imported from RxJS very easily:

```
1 import {Subject} from 'rxjs/Subject';
```

• A subscription can be canceled by calling the unsubscribe method.
